EXECUTIVE SUMMARY

Welcome to the MSC Sustainable Tuna Handbook. This handbook aims to discuss some of the complexities of sustainable tuna fishing and increase the reader’s understanding of global tuna fisheries and the global tuna supply chain. It explains how MSC certified tuna fisheries have achieved a high bar of sustainability, defined by the MSC Fisheries Standard.

This handbook comes at a critical time: with the global demand for tuna increasing over recent decades, the pressure on local populations and ecosystems has also intensified. At the same time, the diversity in the sector has fuelled questions related to gear type and fishing methods, species, sustainability, and environmental impact, to name a few.

For tuna populations to thrive, the sector requires robust and coordinated management, effective enforcement, elimination of forced labour and illegal fishing, reduction in mislabelling, and reductions in catches of Endangered, Threatened and Protected (ETP) species. These issues are prevalent in many tuna fisheries and present sourcing risks that can prove challenging. Furthermore, a lack of information available on tuna fisheries, conflicting sustainability credentials, and powerful NGO campaign messaging combine to further complicate sourcing decisions.

This handbook hopes to bring clarity to these issues and demonstrate how MSC certification can help mitigate these risks, essential to fulfilling sustainable sourcing policies. It is aimed at anyone involved with sourcing sustainable tuna as a reference guide for the various aspects of tuna sourcing.

Over 70% of consumers believe that to save the oceans we should consume seafood only from sustainable sources. The supply chain needs to respond to this demand and ensure that environmental and social threats related to tuna fishing are minimised through sourcing from verifiably sustainable fisheries.

The blue MSC label can help fulfil these commitments by ensuring sustainability against a rigorous and demanding standard and providing traceability from ocean to plate. It is an opportunity to deliver on sustainable sourcing commitments and to ensure a sustainable supply for these iconic species.

While MSC certification provides a solution to sustainable seafood sourcing requirements, we recognise that due to the complex and diverse nature of the global tuna supply chain, coupled with an increase from pressure groups on the sourcing of both non-certified and MSC certified tuna, further information would benefit those operating within the tuna supply chain to help provide greater clarity and knowledge on the global tuna landscape.

In addition to examining fishing gears and methods, species, impacts and issues, this handbook also profiles a range of MSC certified tuna fisheries illustrating how different types of fisheries can meet the MSC Standard, even with varied gear types, fishing methods, species and management approaches. It examines how these fisheries gained their sustainability credentials, including the actions they have taken over time, to achieve and maintain their certification. Common themes include:

- Improved observer coverage
- Improved management to protect tuna stocks in the long term
- Minimising fishery impacts on other species, including overfished stocks and Endangered, Threatened and Protected (ETP) species

While the MSC Standard sets the bar for sustainability of fisheries, it is important to recognise Fishery Improvement Projects (FIPs) as an important aspect of the path to sustainability. As such, this handbook also provides an example of a successful FIP that has progressed to become an MSC certified fishery.

Our vision is to see more fisheries enter MSC assessment at a level at which they can achieve certification. Those already certified to the MSC Standard are leading the way and have made – often considerable – changes to achieve their certification. These leaders are helping support global tuna sustainability. Your support in this movement, and action at the national and international level, is crucial to ensure these fisheries are protected for future generations.

By sourcing MSC certified tuna, you are not only investing in ensuring stable supplies of fish for the future with secure supply chains, but also incentivizing healthy oceans and coastal communities. This handbook will help you navigate this complex and fascinating world.
**INTRODUCTION TO SUSTAINABLE TUNA SOURCING**

**Healthy Stocks**

With increased demand for tuna comes increased pressure on tuna stocks and associated ecosystems. At the moment, most tuna stocks are at healthy levels, but there are significant variations and stocks can change. Retailers seeking to buy from tuna with healthy stocks can rely on MSC certified tuna fisheries, which ensure that the stocks are healthy or are in a robust and demonstrably credible rebuilding plan.

**Environmental Impacts**

Tuna fisheries can be associated with significant bycatch problems, catching and entangling seabirds, sharks and marine mammals. Different fisheries have vastly different impacts depending on how the fishing gears are used (see page 16) and where the tuna is fished.

Retail buyers play a pivotal role in reducing these impacts by sourcing sustainable tuna. Some environmental groups have pressured buyers to source from pole and line fisheries because the bycatch of non-tuna species from this fishing gear is considered minimal. However, focusing on a single attribute, such as fishing gear, is too simplistic: tuna stocks may still be overfished or poorly-managed and particular fisheries, irrespective of gear type, may face other challenges such as the catch of juvenile tuna.

**Management**

Tuna are managed at the international level by Regional Fisheries Management Organisations (RFMOs) (see page 14), but management at this level, involving as many as fifty member countries, can be slow. Retailers can support sustainable tuna by backing strong conservation measures through the adoption of measures such as Harvest Strategies and Harvest Control Rules (HCRs), by RFMOs (see case study on page 29). Sourcing from overfished stocks, or from fisheries that have significant bycatch of non-target species or environmental impacts, creates business and supply chain risks. Businesses therefore have a vested interest in helping to ensure strong conservation measures are adopted.

**Labour**

In addition to these environmental issues, there are also concerns about the scale of forced labour and human rights issues in tuna supply chains. The MSC condemns forced labour and although we were built as an environmental standard, we have taken steps to keeping forced labour out of the MSC certified supply chain (see page 36).

**Reducing Risk**

The best way for tuna buyers to significantly reduce exposure to the above risks is to choose MSC certified tuna. A certified fishery ensures that the stocks are healthy or are in a robust and demonstrably credible rebuilding plan, the impact on the ecosystem is minimal and the fishery is well-managed. What is more, by choosing MSC, you are incentivizing global fisheries to become more sustainable, thereby safeguarding livelihoods and healthy oceans for the future.
THE MSC FISHERIES STANDARD

The MSC Fisheries Standard brings together over 20 years of collaboration with scientists, the fishing industry and conservation groups. It reflects internationally accepted fisheries science and best practice management.

The three principles of the MSC Fisheries Standard

**Principle 1:** Sustainability of the stock: Fisheries must operate in a way that allows fishing to continue indefinitely, without over exploiting the resource.

**Principle 2:** Ecosystem impacts: Fishing operations need to be managed to maintain the structure, productivity, function and diversity of the ecosystem upon which the fishery depends, including other species and habitats.

**Principle 3:** Effective management: All fisheries need to meet all local, national and international laws and have an effective management system in place.

HOW DOES THE SCORING PROCESS WORK?

There are 28 performance indicators in the Fisheries Standard that sit under the three principles.

Your fishery is assigned a score for each performance indicator where 60 is the minimum acceptable performance, 80 is global best practice and 100 is near perfect performance.

To be certified, your fishery must score:

- At least 60 for each of the 28 performance indicators
- An average score of 80 across all performance indicators under each of the three principles

If your fishery scores between 60 and 79 for any performance indicator, you are required to improve your fishery’s performance against that indicator so that it scores 80 or above within five years. This improvement is called a condition.
The Chain of Custody Standard: Default Version has Five Principles

**Principle 1:**
Companies must purchase certified product from a certified supplier.

**Principle 2:**
Certified products are clearly identifiable.

**Principle 3:**
Certified products are separated from non-certified.

**Principle 4:**
Certified products are traceable, and volumes are recorded.

**Principle 5:**
Your management system addresses the requirements of the Chain of Custody Standard.

Do I need Chain of Custody Certification?

The Chain of Custody Standard is a traceability and segregation standard that is applicable to the full supply chain – from a certified fishery or farm, to final sale.

Examples of businesses eligible for Chain of Custody certification:

- A fishmonger serving final consumers and caterers
- A seafood company with a trading office, processing facility and storage unit

When Chain of Custody certification is not needed:

- Your company buys pre-packed, labelled certified products that will be sold to the end consumer without being opened, re-packed or re-labelled. Such items are known as consumer-ready tamper-proof products. Retail packages of frozen fish fingers or tins of smoked mackerel fillets are examples of consumer-ready tamper-proof products.
- Your company buys certified products but does not wish to sell these on as certified. In this case the chain of custody is broken and your customers may not make any claims about the product being certified.
- Your company does not take legal ownership of certified seafood. This may be the case if your company provides contracted services for certified companies and therefore can be covered by your customer’s Chain of Custody certificate as a subcontractor.

Businesses not eligible for Chain of Custody certification:

- A company that has been successfully prosecuted for a forced or child labour violation in the last two years
- A company whose certificate was withdrawn for a breach of Chain of Custody in the last two years
- A company whose certificate was suspended in the last six months
- Enhanced fishery or farm operations that are out of scope of the MSC Fisheries Standard or the ASC Farm Standard
TUNA SPECIES

Worldwide there are 23 stocks of the major commercial tuna species: 5 skipjack, 4 yellowfin, 4 bluefin, 6 albacore, and 4 bigeye stocks. A recent report from the International Seafood Sustainability Foundation (ISSF) showed that 65% of tuna stocks were at healthy levels, 17.5% were overfished and 17.5% were at an intermediate level. This page shows important differences between the five major commercial tuna species (in alphabetical order). Their differences not only impact their susceptibility to overfishing, but also their taste, price and availability.

Albacore tuna
Albacore grows more slowly than other tunas such as skipjack and yellowfin and matures later at around 5 years. It is typically caught in deeper waters, around 400m deep and is found in the Pacific, Indian and Atlantic Oceans, the Mediterranean and even in UK waters.

Albacore represents 5% of the world’s tuna catch and is also known as ‘white tuna’ due to its light flesh. It is ideal for canning, due to its dryer texture but is also sold as fresh steak or in jars with olive oil. Albacore is significantly more expensive than skipjack.

Bigeye tuna
Bigeye is a large tuna that also grows more slowly than yellowfin or skipjack, but matures relatively young, around three years. It is found in the Indian, Pacific and Atlantic Oceans and represents 8% of the world’s tuna catch. Because bigeye typically live at deeper depths, compared to yellowfin and skipjack, they have a thick layer of fat to insulate them from the colder water. This fat adds moisture, that makes bigeye attractive for sashimi markets.

Bluefin tuna
There are three bluefin species in four stocks: Western Atlantic, Eastern Atlantic and Mediterranean, Pacific, and Southern. Atlantic bluefin is the largest tuna species, and they take a long time to grow and reproduce. Some can only reproduce from the age of 15, therefore their populations are slow to recover from overfishing. Bluefin represent just 1% of the world’s tuna catch. Due to their higher fat content, they are normally eaten as sashimi. Bluefin are highly-prized and regularly set new sales records in Japanese auctions – one fish sold for 333.6 million Yen (over 3 million US dollars) in Tokyo’s fish market in early 2019.

Skipjack tuna
Skipjack is the smallest and most abundant of the commercial tuna species. They reproduce quickly and are highly productive, maturing around 1-2 years of age. Skipjack are caught in the tropical waters of the Pacific, Atlantic and Indian Oceans. It is the most popular and generally the most affordable of the tuna species, representing 58% of the world’s tuna catch. Its small size provides small loins and chunks, which make them a popular fish for canning.

Yellowfin tuna
Yellowfin are a similar sized tuna to bigeye but mature at around 2 years old. They reproduce throughout the year making them highly productive. They are found throughout the Pacific, Indian and Atlantic Oceans and represent 29% of the world’s tuna catch. Yellowfin meat is firm with a mild taste and can be canned or sold as fresh or frozen fillets.
The Tuna Challenge: International Tuna Governance and Management

In an effort to bring coordinated international management to tuna stocks and ensure sustainable fisheries, five tuna Regional Fisheries Management Organisations (RFMOs) were established around the world in the 1990s and 2000s. These organisations each comprise between 21 and 50 member countries, which are the countries historically involved in catching the tuna and those in whose waters the tuna live. While RFMOs were designed so that member states could jointly develop and set sustainable management measures to prevent overfishing of tuna, in many cases these bodies have struggled to deliver on their sustainability commitments. A key reason is that most decisions in RFMOs require consensus. Finding agreement amongst as many as 50 member states – with conflicting priorities and interests – is incredibly challenging.

MSC requires the adoption of HCRs to move from ‘generally understood’ HCRs to ‘well defined’ HCRs.

In an effort to bring coordinated international management to tuna stocks and ensure sustainable fisheries, five tuna Regional Fisheries Management Organisations (RFMOs) were established around the world in the 1990s and 2000s. These organisations each comprise between 21 and 50 member countries, which are the countries historically involved in catching the tuna and those in whose waters the tuna live.

The need for consensus makes decision-making slow and tends to lower the bar to the lowest level of management accepted by all members. This can be especially problematic when there is an urgent need to reduce fishing pressure on a tuna stock that is being overexploited. Management by consensus can, at times, provide a veto to any individual member state.

One way to ensure an appropriate response to declining tuna stocks is the agreement, implementation and enforcement of robust Harvest Control Rules (HCRs). HCRs are pre-agreed actions in response to changes of stock status. Agreeing HCRs is politically challenging given the varied perspectives and priorities of the participating coastal states. However, consensus can be achieved more readily when stocks are healthy, so it is important to have HCRs in place even when stocks are perceived as healthy, so any management action can be applied quickly when needed. For example, if a stock falls below a certain level, the total allowable catch can be reduced by a pre-defined amount to ensure future harvests are set at sustainable limits.

To date, four of the five tuna RFMOs have agreed HCRs for particular tuna stocks:
- In 2016, the IOTC agreed a landmark HCR for skipjack (see case study on page 29)
- The IATTC has agreed on an HCR for yellowfin and bigeye in the Eastern Pacific Ocean
- The CCSBT agreed an HCR for southern bluefin
- In 2018, ICCAT adopted an HCR for North Atlantic albacore

Movement towards HCRs on other stocks remains slow, but most RFMOs have plans to deliver these important management measures within the next five years.

Along with our partners, the MSC is pushing for stronger action from RFMOs including coordinating timelines for certification conditions. The adoption of robust, well defined HCRs is a requirement for the ongoing certification of MSC certified tuna fisheries. Therefore, as more fisheries have become MSC certified, increasingly, RFMOs are being encouraged to adopt and implement responsive harvest strategies that include well-defined HCRs. Retailers can help RFMOs to adopt HCRs by encouraging the member delegations to support their adoption in RFMO meetings.

MSC requires the adoption of HCRs to move from ‘generally understood’ HCRs to ‘well defined’ HCRs.

To prevent overfishing, the MSC program requires the adoption of Harvest Control Rules (HCRs), moving from ‘generally understood’ HCRs to ‘well defined’ HCRs, within an agreed timeframe. HCRs are a set of pre-agreed, well-defined actions used to determine how much fishing can occur, based on the health of a tuna stock. When stock levels reach certain thresholds, the HCR would inform the RFMO response to prevent overfishing, before the population declines further. Agreeing ‘well defined’ HCRs in advance is considered best practice as it allows the management bodies to avoid overfishing by acting in a timely and agreed way. In early 2019, the HCR conditions for all MSC certified tuna fisheries were aligned, so that multiple certified fisheries in the same region can work to the same timeframes and can coordinate their efforts for the adoption of robust harvest strategies supported by well-defined HCRs.

See pages 28 and 29 on Harvest Control Rules and to read about how the Indian Ocean Tuna Commission agreed to implement HCRs.
TUNA FISHING GEARS

The various gear types used to catch tuna have different impacts and impacts are also specific to individual regions. The impacts depend on the species, habitats and the natural environment of a given area and how the fishing gears and fishing operations are modified to reduce their impacts. Even gear types that are seemingly benign can have negative impacts on the environment.

Due to the varied nature of tuna fisheries, every fishery needs to be individually assessed, taking into account fishing gear impacts on the ecosystem, stock status and management practices. The MSC Fisheries Standard requires rigorous monitoring and management programs for certified fisheries, to ensure both the target stock and the ecosystem remain healthy.

In line with United Nations Food and Agriculture Organization (UNFAO) guidelines, the MSC program is open to all types of wild-capture fisheries regardless of their size, fishing technique or location. The impact of a fishing gear should be based on evidence for that specific fishery, rather than its perceived challenges or benefits. The only exceptions are fishing with explosives or poisons, which are excluded from the MSC program.

Tuna are caught by a variety of gear types and fishing methods (see page 18). Purse seine, gillnet, and pole and line are used to catch tuna near the surface e.g. skipjack and small yellowfin, albacore and bluefin. Deep-set longlines are used to catch tuna in deeper waters e.g. larger bluefin, bigeye, yellowfin and albacore9.

Source: 4

PROPORTION OF TUNA CATCH CAUGHT BY GEAR TYPE

- 66% Purse seine
- 10% Longline
- 8% Pole & line
- 4% Gillnets
- 12% Miscellaneous

*Miscellaneous gears are not fully defined but include handline, abalone-noodling and tuna traps.
In pole and line fishing, fishermen locate a school of tuna, then may scatter small live bait fish and spray water onto the sea surface. This creates the illusion of an active school of prey, sending the tuna into a feeding frenzy, where they will bite anything they see. Fishermen then line up, equipped with hand-held poles with barbless hooks. Once a tuna bites, the fisherman flicks it up over their head and onto the deck. Like in purse seine fishing, pole and line fishing can also be used to catch fish that congregate around FADs, or on ‘free schools’ of tuna (see page 20-25). Pole and line fishing represents 8% of global tuna catches but they are used for catching 30% of North Pacific albacore and 20% of Indian Ocean skipjack.

Trolling is a type of handline fishing. A slow-moving boat tows multiple (10 to 20) fishing lines that are baited with hooks used to lure in the fish. The lines can be hauled in by hand or mechanically. Whilst trolling represents less than 12% of tuna catches worldwide, it is used to catch 18% of Atlantic Ocean northern albacore and 21% of North Pacific albacore.

“A different fisheries have vastly different impacts depending on how the fishing gears are used and where the tuna is fished.”

Bill Holden, MSC Senior Tuna Fisheries Outreach Manager
**FISHING METHODS: FISH AGGREGATING DEVICES AND FREE-SCHOOL FISHING**

Tuna are highly migratory, ranging over thousands of miles. Some fishermen track tuna or follow these migrations to catch the tuna schools, this is called ‘free school’ fishing. Other fishermen use objects to help them locate and catch the tuna more easily, called Fish Aggregating Devices (FADs). This section discusses both of these methods and any associated environmental impacts.

Purse seine nets and poles and lines are set and deployed on free-swimming schools of tuna, which are not associated with floating objects or other marine life. This can result in lower bycatch, but also smaller catches, compared to nets or lines that are set on schools of tuna associated with FADs.

The following graph shows differences in average bycatch rates found between the FAD and free-school tuna fisheries. Data is not available on the differences in bycatch rates for specific gear types.

Various environmental NGOs, including Greenpeace, have campaigned to support free-school fishing because of the lower levels of bycatch. While free-school sets do have a range of benefits, there are also some drawbacks, including:

- There is no internationally-accepted distance that a fishing boat has to be from a FAD to count as ‘free-school’ fishing, but distances can range from 1 to 5 nautical miles. This could result in fishing being conducted on a FAD-associated school of tuna even though the fishery purports to be fishing using free-school methods.

- Given the time needed to find the tuna schools, it is expensive, so fishing boats typically also fish using FADs on the same trip.

After consulting the industry, environmental NGOs and fishing experts, the MSC recently updated its requirements so that from March 2023 purse seine tuna fisheries catching free-school tuna and tuna associated with Fish Aggregating Devices (FADs) will need to seek certification for their entire catch (see page 39 Unit of Assessment). The MSC is already working with the International Sustainable Seafood Foundation (ISSF), tuna fisheries and scientists to support these fisheries to improve the use and management of FADs to meet the high bar for sustainable fishing set by the MSC Standard.
FISH AGGREGATING DEVICES (FADs)

Due to their highly-migratory nature, it can be extremely difficult for fishermen to locate a tuna school.

Many fish species including tuna, are attracted to, and aggregate around, floating objects in the ocean. Firstly, small fish are attracted to the structure of the FAD, and in turn, this attracts bigger pelagic fish such as tuna. As a result of this natural behaviour, the fishing industry developed Fish Aggregating Devices (FADs) to make finding and fishing tuna easier.

FADs are modified natural or man-made floating objects, often floating wooden structures with hanging nets, used to attract fish. Once the fish are aggregated, the fishermen deploy nets or cast fishing lines close to FADs to catch the tuna. FADs can be drifting or anchored, entangling or non-entangling, and can be made from biodegradable materials (still in the experimental-development phase). All have different impacts on the environment depending on where and how they are used. FADs are used in 65% of purse seine sets and in 40% of the world’s skipjack catch.

Impacts of FAD Use

FADs, particularly those that are left to drift on the high seas, are highly controversial because of their potential impact on the marine environment. This poses a risk to the sustainability of tuna fisheries because marine life can become entangled in the nets that are attached to some designs of FADs.

The aggregation of species other than tuna beneath FADs also makes them more likely to be caught as bycatch in the same nets or lines used to catch tuna. This causes concern among NGOs, creates apprehension about sourcing from fisheries that use FADs and therefore requires greater assurances of the sustainability of tuna caught in association with FADs.

Other issues with drifting FADs include their potential effects on tuna migration and the materials they are made from: if a FAD becomes lost or derelict, it can damage corals or contribute to ocean plastic. This is problematic because there are an estimated 90,000-120,000 FADs worldwide, so their cumulative impact can be damaging if not managed effectively.

FAD Improvements

Some segments of the tuna fishing industry – in partnership with research institutions – are developing measures to reduce the impact of FADs through technological improvements in FAD design, which have advanced considerably over recent years. For example, some fisheries are adopting the use of biodegradable and non-entangling drifting FADs to reduce their persistence in the marine environment and reduce the entanglement of non-target species.

These efforts, combined with improved tracking and data collection, licensing and registration of FADs, monitoring and retrieval of old FADs, and purse seine gear modifications, have enabled fisheries using FADs to reduce their non-target bycatch to levels at which MSC certification is a possibility.

These improvements led to the first tuna fishery using drifting FADs to achieve MSC certification in 2018. Working with the Indian Ocean Tuna Commission and Seychelles authorities, the Echebastar purse seine tuna fishery has actively sought to reduce bycatch of non-target species by reducing numbers of FADs, deploying only non-entangling FADs and ensuring the rapid release of non-target species. These efforts demonstrate leadership within the tuna fishing industry. Now certified, this fishery will also be required, as a condition of its certification, to invest in research and practices to further reduce the potential impacts of FADs and better understand their impacts (see case study, page 58).

With advances in FAD design, monitoring and management, and new requirements for a purse seine tuna fishery’s entire catch to be MSC certified, we expect to see more tuna fisheries using FADs to achieve MSC certification in the next few years. The MSC is working with fisheries and other organisations to help them to understand what needs to happen to ensure the long-term sustainability of these fisheries.
MSC certification is based on comprehensive assessment of the impacts of a fishery and the environment within which it operates. Following UNFAO guidelines any fishing gear, except explosives and poisons, is eligible to be assessed under the MSC program. Therefore, the MSC does not explicitly exclude fishing vessels that set on FADs from being certified. However, any fishery with high non-target bycatch or impacts from lost FADs will need to make improvements to meet the MSC Standard’s minimum criteria for environmental impact (Principle 2) and achieve certification.

Natural FADs
Some tuna fisheries target natural structures or floating objects, including free-floating logs (tree trunks) and large marine animals, such as whale sharks, around which fish congregate. This is referred to as ‘natural-associated’ or ‘object-associated’ fishing.

Risks: Because gear set on natural FADs may be close to large marine animals, it can result in bycatch.

Mitigation: Due to the impact on whale sharks in the Parties to the Nauru Agreement tuna fishery (see case study on page 66), the fishery banned setting purse seine nets on whale sharks in 2012. Other fisheries require a set distance between the natural FAD and where fishing gear can be deployed.

Used In: No MSC certified fisheries set on logs or whale sharks.

Anchored FADs
The FAD is a raft – often made of bamboo – fixed to an anchored buoy, usually in coastal waters. Anchored FADs (often referred to as aFADs) can be either non-entangling or entangling. They are used by both commercial and subsistence fisheries and are most commonly associated with pole and line fishing. The FAD stays in the same position and doesn’t drift, reducing the risk of it getting lost or damaging reefs.

Risks: These FADs can be anchored in vulnerable habitats, such as corals and can be associated with catching juvenile yellowfin. Some anchored FADs also include entangling nets which can result in non-target species being caught in the FAD nets.

Mitigation: Anchoring in vulnerable habitats can be avoided. Fishermen can relocate their fishing if too many juveniles are being caught in a particular area.

Used In: MSC certified Maldives pole and line skipjack fishery, MSC certified Solomon Islands skipjack and yellowfin purse seine and pole and line fishery, PT Citraraja Ampat, Sorong, skipjack and yellowfin.

Biodegradable FADs
Several companies are currently testing non-entangling, biodegradable FADs to reduce the impact of discarded FADs on coral reefs and to reduce the rate of plastics entering the ocean. These are currently at the experimental stage.

Drifting FADs (dFADs)

Non-entangling dFADs
Non-entangling dFADs drift with ocean currents and winds. Non-entangling dFADs use ropes or rolled up nets to avoid entangling marine creatures. Each dFAD has a buoy with a reference number and a GPS unit so the fishermen can find them.

Risks: Evidence is still needed to fully determine the impact of lost dFADs.

Mitigation: Non-entangling dFADs can be designed to reduce the risk of entangling animals. The first certified fishery to use dFADs in 2018 uses 100% non-entangling dFADs.

Used In: MSC certified Echebastar purse seine skipjack fishery.

Entangling dFADs
Entangling dFADs have nets that hang in the water column from a floating structure. They can be anchored to the seabed or drift on the high seas.

Risks: The nets serve to attract a greater variety of animals and can result in them being caught. The dFADs can be constructed using a variety of materials. The ones that have open nets hanging from the raft tend to have the highest rates of entanglement.

Mitigation: Entangling dFADs can be modified e.g. by rolling the nets up into ‘sausages’, to reduce the risk of entangling other animals.

Used In: No MSC certified purse seine fisheries use entangling dFADs.
CONSIDERATIONS IN SOURCING TUNA

STOCK STATUS

Worldwide there are 23 stocks of the major commercial tuna species (6 albacore, 4 bigeye, 4 bluefin, 5 skipjack and 4 yellowfin stocks). A recent report from the ISSF shows that 65% of tuna stocks are at a healthy level of abundance, 17.5% are overfished and 17.5% are at an intermediate level.

How MSC certification addresses stock challenges

Principle 1 of the MSC Fisheries Standard asks: Are enough mature fish left in the ocean to breed? Fishing must be managed at a level that ensures it can continue indefinitely and the fish population can remain productive and healthy. For those stocks that are depleted, fishing must be conducted in a manner that demonstrably leads to their recovery.

One of the six questions in Principle 1 looks at the size of the total fish stock. For a fishery to be certified without conditions, the target fish stock – the amount of mature fish in the stock – must be at (or around) a level consistent with Maximum Sustainable Yield (MSY).

What is MSY?

In population ecology MSY is the largest average yield (catch) that can theoretically be taken from a species’ stock over an indefinite period under constant environmental conditions. It is usually measured in tonnes. To have a viable and thriving fishing sector, the size of fish stocks must be at, or above, levels where they can produce the maximum sustainable yield over an indefinite timeframe.

The state of stocks in MSC certified fisheries

A study of over 100 fisheries across the world showed that stocks targeted by MSC certified fisheries are often healthier and under less fishing pressure than others managed in the same region. Nearly three quarters of certified stocks included in the study were at or above the MSY level, compared with less than half of uncertified stocks.

A smaller group of stocks targeted by certified fisheries were below the MSY level, but above the biological limit for recovery, i.e. the minimum amount of fish needed for a stock to be able to rebuild to healthy levels. Fisheries on these stocks are required to show that stocks are rebuilding in order to remain MSC certified. For example, the North Atlantic albacore stock reduced catches by setting a conservative Total Allowable Catch to rebuild the stock back toward sustainable levels. Following the rebuilding, the stock now has a well-defined HCR in place to maintain it at a sustainable level, consistent with MSY.

THE HEALTH OF TUNA STOCKS AROUND THE WORLD

Stock is at or above BMSY*

Stock below BMSY but it has been stable, increasing, or fluctuating around SSBMSY** because the stock is being managed at FMSY***. Yellow is also used in the absence of a stock assessment.

Stock is below BMSY and it has not been stable, increasing or fluctuating around BMSY.

◊ The latest stock assessment for yellowfin in the Eastern Pacific is subject to high uncertainty and a new stock assessment model is due to be released later this year.

According to ISSF, skipjack stocks, which make up more than half of global catches, are generally healthy. The Pacific bluefin stock is overfished, with evidence of recovery existing for the Southern Bluefin, and for both eastern and western stocks of Atlantic Bluefin there is uncertainty on stock status but overfishing is not occurring. Albacore stocks are generally healthy, with uncertainty in the Mediterranean stock assessment resulting in a yellow rating, but some yellowfin stocks are declining or overfished. 15% of the total tuna catch comes from stocks where fishing is not well managed.

Global catch of tuna has tended to increase consistently, from less than 0.6 million tonnes in 1950, to more than 6 million tonnes today (UN FAO). With these trends continuing there is an urgent need not only to reduce fishing pressure on those stocks already overfished, but to protect and effectively manage those currently in a healthy state.

* BMSY is the biomass associated with the Maximum Sustainable Yield (MSY), where the biomass is simply the body weight of all the fish of one specific stock in the water. Biomass is measured in tonnes. MSY is the largest yield of fish that can be caught from a specific fish stock over an indefinite period under constant environmental conditions.

** SSBMSY is the Spawning Stock Biomass (SSB) associated with the MSY.

*** FMSY is the fishing mortality rate consistent with achieving the MSY.
Harvest strategies and Harvest Control Rules (HCRs) define how catches should be reduced if a fish stock declines. HCRs are recognized as best practice in fisheries management. They are tied to scientifically derived reference points and are incorporated in the MSC Fisheries Standard.

A fish stock usually declines because the number of young fish coming into the population has been low or catches have been too high. This is like a business that finds itself with lower sales than expected, or higher expenditures. Either circumstance can damage the company’s balance sheet and put it at risk. If the board of a business does not react rapidly, the business can go bankrupt. The business needs to respond quickly when stocks decline. RFMOs need to respond quickly when stocks decline.

HCRs that are pre-agreed, well defined and scientifically tested can be triggered much faster, and with more reliable effect, than simply responding to the need for well-defined harvest strategies and HCRs.

Harvest strategies and HCRs for most stocks set within their work plans by the early 2020s. To date, four of the five tuna RFMOs have agreed HCRs for particular tuna stocks. Other tuna fisheries in the MSC program aligned their HCR conditions in spring 2019, accelerating some, and extending others, so that multiple certified fisheries in the same region could coordinate their efforts.

At present, the majority of MSC certified tuna fisheries have a condition to adopt well-defined HCRs (see previous page). Therefore, as more fisheries become MSC certified, increasingly, RFMOs are being encouraged to adopt HCRs.

Along with our partners, the MSC is pushing for stronger action from RFMOs. Retailers can encourage RFMOs to adopt harvest strategies and HCRs by encouraging the member delegations from each country to support them in RFMO meetings.

Empty cells are those stocks where there is no HCR and no fisheries are MSC certified at the time of writing.
Fish live in multi-species communities, so wherever there is fishing it is always possible there could be some incidental capture of non-target species i.e. those species that the fishery did not intend to catch.

It is also common for fisheries to target more than one species at a time due to market demands, profitability and the availability of different species. This is especially common in mixed fisheries, where many species are caught in one area or type of fishery e.g. trap fisheries.

To be MSC certified, fishing activity must not have a long-term detrimental impact on the population of any marine species.

Non-target species that are caught may be considered as ‘bycatch’ (because they are not the main target species), but they may still be retained if they are considered valuable (either for commercial reasons, or for subsistence). Either way, it is important that all species, including non-target species, are managed effectively and there is good information about their population status and impacts.

MSC certified fisheries are required to investigate and minimise bycatch wherever possible. This is especially true for interactions with Endangered, Threatened and Protected (ETP) species, such as turtles and some shark and seabird species. Conditions set for MSC certified fisheries have resulted in significant reductions to the level of bycatch and interactions with ETP species. For example, the Western Australian rock lobster fishery which, following improved research, reduced interactions with sea lions to zero. Also, since becoming MSC certified, the South African hake fishery has reduced interactions with albatross by 99% and the Fiji albacore tuna fishery has implemented measures to reduce bycatch of sharks.

A fishery’s impact on ETP species should always be minimised. Catching these species should be avoided (by implementing measures to minimise the chance of their capture). When they are accidentally caught, handling practices should be implemented to ensure their safe release and to maximise their chance of survival.

A new requirement was added to the most recent version of the MSC Fisheries Standard (version 2.0, effective from 2015) for fisheries to regularly review alternative bycatch mitigation measures and implement them wherever appropriate.
**SHARK FINNING**

Shark finning is the practice of removing any of the fins of a shark (including the tail) while at sea and discarding the remainder of the shark at sea (MSC-MSCI Vocabulary vs.3 (2020)). It is prohibited within MSC certified fisheries.

Because sharks are slow-growing, long-living fish that usually produce few offspring, many species are at high risk of overfishing. A high demand for shark products makes them even more vulnerable, with an estimated 40-176 million sharks being traded in 2000 after being finned.

Requirements to demonstrate that shark finning is not taking place in a certified fishery were introduced into the MSC Standard in 2013. We have seen a dramatic decline in incidents of shark finning within MSC certified tuna fisheries. For example, the MSC certified PNA purse seine skipjack fishery achieving a 99% reduction between 2013 and 2019 (see case study on page 66).

Our current requirements mean the vessel of any company or fisher convicted of shark finning will not be eligible for MSC certification for at least two years. If evidence of shark finning is detected during an audit or assessment, the fishery faces suspension unless it can show the offending vessel has been expelled from the certificate. This strengthens the MSC's commitment that certified fisheries are not engaged in shark finning whilst ensuring that a whole fleet does not lose its MSC certification because of the actions of one member.

Shark finning is also being considered as part of the Fisheries Standard Review. This will look at the measures that fisheries have in place to ensure that shark finning is not occurring, including how widely Fins Naturally Attached policies have been adopted and if the MSC's requirements need to change in order to continue to reflect global best practice.

A preliminary survey of global fishery managers and governments in 2019 found that 14 out of the 25 management agencies that responded had a Fins Naturally Attached policy. The Review will conclude in early 2022, following consultation of stakeholders on possible changes to the MSC Fisheries Standard.

Find out more and contribute to the MSC Fisheries Standard Review at [msc.org/fsr](http://msc.org/fsr)
Transshipment is the transfer of seafood catch between a fishing vessel and a carrier vessel at sea or in port. Transshipment is an important part of fishing supply chains, enabling fishing vessels to spend their time fishing at sea, rather than transporting fish to what may be distant ports, allowing the fishing activity to be more efficient.

Since tuna account for around 61% of the total high seas catch (by volume) and they are one of the more popular species for transshipping on the high seas, a considerable proportion of tuna may undergo transshipment. Longlines are one of the gear types more likely to be involved in transshipment, as the vessels often lack the deep-freezing facilities to maintain the high-quality products.

However, transshipment can be associated with IUU fishing, as it can be a means of concealing the true origin of catches. It is estimated that in the Western and Central Pacific Ocean alone, at least US$142 million worth of tuna and tuna-like species are moved in illegal transshipments each year. Of course, there are huge variations in monitoring and visibility and the risk of IUU fishing varies enormously by flag state and even by fishing gear.

To prevent this, some RFMOs have restricted tuna transshipment to ports or have prohibited certain vessels from transshipping and there are controls required for high seas fisheries e.g. observers on vessels, agreed transshipment locations and controls by flag states. However, to prevent illegal transshipments, the transfer of tuna needs to be documented throughout the supply chain (at-sea and in port), collecting data on the catch, the catch method and information about the transshipment. Whilst these documents are usually found to be available when the fish are landed directly into ports, the documents are often found to be less precise or incomplete when the fish are transshipped, particularly in long supply chains. These data gaps can complicate sustainable sourcing decisions and, therefore, the MSC requires that certified seafood is traceable in all steps of the supply chain.

The MSC’s requirements for traceability both at sea and on land in relation to IUU fishing help to mitigate these issues. MSC certified fisheries must not be involved IUU fishing, certified catch must be clearly documented and segregated from non-certified catch and certified fish must not be purchased from or carried on vessels that have been blacklisted by international fisheries management bodies for engaging in IUU fishing.

Many NGOs have also expressed concern that, by removing the need for fishing vessels to return to land, transshipment increases the risk of forced and bonded labour violations. Since 2014 any organisation prosecuted for forced labour violations in the last two years has been ineligible for MSC certification, and since 2018 all certified fisheries have been required to detail measures on their actions to mitigate the presence of forced or child labour.

Illegal, unreported and unregulated (IUU) fishing is where fishing is conducted counter to the management measures in that jurisdiction. It includes vessels fishing without a licence for a particular area, vessels with a licence but fishing in excess of their established quotas or using prohibited gear types or fishing methods.

As part of the MSC’s commitment to the UN Sustainable Development Goals (SDGs), the MSC is committed to eliminating IUU fishing in certified fisheries to the point where: it is non-existent, or where IUU does exist, it is at such a low level that the fishery management, including assessments and the estimation of IUU impacts on harvested species and the ecosystem, can maintain affected populations at sustainable levels.

**IUU fishing:**
- Depletes fish stocks
- Destroys habitats
- Disadvantages honest and legitimate fishermen
- Weakens coastal communities (particularly in developing countries)
- Undermines legal markets and reinforces illegal ones (IUU is estimated to be worth US$10-23.5 billion annually)

Tuna species are vulnerable to IUU fishing: tuna can be an extremely highly-prized and valuable species, caught in high seas where they are difficult to monitor. Once tuna enters international trade it is essentially a commodity, and illegally-caught fish can be easily concealed if traceability systems are not in place. Of course, there are huge variations in monitoring and visibility and the risk of IUU fishing varies enormously by flag state and even by fishing gear.

Forced Labour

“Around the world, more than 150 million children and 25 million adults are involved in forced labour. We recognise the urgency in addressing forced and child labour violations and have put measures in place to tackle this issue in the supply chain for certified seafood.”

Dr Yemi Oloruntuyi, MSC Head of Accessibility

Labour abuse in the seafood supply chain has become an increasing area of focus with media reports exposing exploitative labour practices, including slavery and human trafficking. Forced labour is a particular concern in the catching sector, where vessels and their crews can spend long periods at sea, beyond the reach of enforcement agencies, without the applicable worker protection legislation and where crew members have limited access to communication methods and external support. This is an industry-wide issue with no quick or easy solution.

The MSC condemns the use of forced or child labour. While our focus is on environmental sustainability, we recognise concern for this issue and have worked with other organisations focused on this problem to help develop practical solutions.

In 2014, the MSC Board made a commitment to include a clear policy on forced labour and entities prosecuted for forced labour violations in the previous two years were excluded from the MSC program. The MSC went on to hold multi-stakeholder consultations with more than 300 organisations on this topic between 2016-2018.

The MSC has since introduced further measures to its Chain of Custody and Fisheries Standards to provide greater assurance on labour conditions within the MSC certified supply chain, and to contribute to improved understanding of this complex issue.

As of August 2019 all fisheries in the MSC program are required to complete a template detailing the measures they have in place to mitigate the presence of forced or child labour. These declarations are publically available on MSC’s website to buyers, governments and NGOs looking for further information of worker welfare within responsibly managed fisheries.

In September 2019, new auditing requirements came into place for all Chain of Custody certificate holders. All MSC Chain of Custody certificate holders will now be required to undergo an independent labour audit unless they can demonstrate that they are at ‘lower risk’ of practising forced or child labour.

To determine if a labour audit is necessary, auditors will assess supply chain companies to see what level of risk there is of labour violations occurring during processing, packing or repacking, and manual offloading in the country or countries they operate in. If a country is considered ‘lower risk’, according to two or more of the following indicators, then the site does not require a labour audit:

- Country Risk Assessment Process for SA8000
- International Trade Union Confederation Global Rights Index
- Ratification of five or more UN conventions on forced or child labour, human trafficking or seafood/fishing
- US Department of Labor List of Goods produced by forced or child labour

These indicators are globally recognised, transparent and commonly used in the seafood industry and were carefully selected through a multi-stakeholder consultation process.

Where required, labour audits must be on-site, conducted by an independent third-party social auditor and use one of three labour audit programs recognised by the MSC: amorfi BSCI audit; SEDEX – Sedex Members Ethical Trade Audit; and SA8000 Certification from Social Accountability International. Certified companies that fail to address identified labour violations within 30 days will have their MSC certificates suspended.
Traceability goes hand-in-hand with sustainability: a traceability system is the best method to prevent fraud and illegal products from entering the supply chain as certified product\(^3\). It helps protect consumers and the efforts of everyone working hard to keep our oceans healthy\(^4\).

A traceable supply chain is key to delivering the MSC’s vision of healthy oceans and providing its consumers with sustainable seafood they can trust\(^4\).

The MSC program is the only certification program of its kind to offer ocean-to-plate traceability through supply chain certification. The MSC Chain of Custody Standard requires that MSC certified seafood is kept separate from other seafood, and can be traced through the entire supply chain, thereby ensuring its certified sustainable origin\(^5\).

Mislabelling is where incorrect information is applied to a product. Mislabelled seafood may involve the substitution of other species, including lower-value or even endangered species\(^7\).

Higher rates of mislabelling have been identified among premium foods (where the potential gains are higher) and in restaurants or take-away outlets (where labelling on the final product may be sparse\(^9\)).

Of the tuna species, mislabelling is highest for bluefin (between 50% and 100% is mislabelled), due to its high value\(^2\). In the UK, for example, mislabelled skipjack has been recorded as being substituted with yellowfin and bigeye, to hide illegally-caught fish\(^7\). DNA testing has revealed that MSC labelled seafood has almost no cases of species mislabelling\(^8\).

In an MSC assessment, a unit of assessment is defined by the target stock, fishing method and practice, vessel type or gear and fishing fleet. It defines the catch that will be assessed and that may subsequently enter the supply chain as MSC certified.

The MSC’s current requirements, valid until 25 September 2020, allow fishing vessels to catch both certified and uncertified catch of the same species during the same fishing trip, provided catches are carefully separated, documented and verified – known as ‘compartmentalisation’\(^3\).

Most market-based programs allow compartmentalisation with the intent that over time, market demand for sustainable products will result in producers favouring certified production, making improvements to their overall operations.

However, stakeholders expressed concerns that these requirements could undermine the overall sustainability of a fishery, particularly in relation to purse seine tuna fisheries catching both MSC certified free school tuna and non-certified tuna around dFADs.

Listening to these concerns, the MSC recently reviewed its requirements relating to compartmentalisation.

Following consultation with fisheries, NGOs and conformity assessment bodies, in March 2020, the MSC announced a change to its definition of a unit of assessment, resolving this issue. The terms ‘fishing practice’ and ‘fishing method’ have been removed from the definition. This means that all individual fishing practices or methods using the same gear type will now need to be assessed as part of the unit of assessment.

Purse seine tuna fisheries catching free-school tuna and tuna associated with fish aggregating devices (FADs) will need to seek certification for their entire catch. The new requirements apply for all new fishery assessments from 25 September 2020, and from 25 March 2023 for already certified fisheries and assessments that started before 25 September 2020.
**RESPONSIBLE AND SUSTAINABLE SOURCING CLAIMS: A UK CASE STUDY**

Buyers can minimise risks in their supply chain by examining individual fisheries and choosing fisheries to source from based on a comprehensive assessment of all aspects of the sustainability, management and potential environmental impacts of the fishery. However, with the variety of challenges and complexity in fisheries, it can be difficult for the buyers to understand and investigate all potential risks. Supply chain organisations have measured ‘sustainability’ using different metrics, which has resulted in inconsistent consumer-facing claims. For example, in the UK terms such as ‘sustainably sourced’ and ‘responsibly sourced’ have been used with different definitions and frameworks behind them, creating an inconsistent consumer message.

To show the difference between responsible and sustainable sourcing, and to make sourcing strategies more robust, organisations such as the Sustainable Seafood Coalition (SSC) based in the UK produced guidelines and codes of conduct for sourcing and labelling to align sourcing requirements and to create common definitions. Similar schemes are in development in other parts of the world.

According to these codes, responsible and sustainable are not the same thing. Responsible sourcing requires assessments to be conducted by the purchaser, to trace the fish to its origins and establish the risk profile of the species including: legality of fishing operations, status of the stock, management practices and wider environmental impacts. This determines a low, medium or high-risk rating of the species and fishery. From there, sourcing and claiming decisions need to be made according to the risk rating and whether improvements are needed within the source fishery. Only when this process has been completed, can a responsible sourcing claim be made.

Sustainable sourcing claims are backed up by certification to a third-party standard, such as MSC. They do not require the same self-completed risk assessment, as the source fishery has already demonstrated and been certified as sustainable. Providing that traceability or chain of custody is in place, then sustainably sourced claims can be made on the final product.

In the UK, the majority of the retailers are members of the SSC. Under the SSC codes of conduct, members can only claim a wild-caught product is sustainable if it meets the principles of a recognised international standard and there is an independently audited chain of custody in place. In effect that means it requires either an independent third-party audit or certification and that fully audited traceability is in place to claim a product is ‘sustainable’. Most commonly this is MSC certified product. Products without an independently audited chain of custody cannot be described as sustainable.

The SSC code of conduct also allows for claims of responsible sourcing, where for example the product is sourced from a Fishery Improvement Project (FIP), so long as a risk assessment has been conducted of that source fishery and it meets key criteria as laid out by the SSC sourcing codes of conduct.
Fishery Improvement Projects (FIPs) are a vital step towards sustainability. They are aimed at assessing and improving a fishery’s sustainability and potentially achieving MSC certification using the MSC Fisheries Standard as a performance benchmark. With a growing demand for sustainable seafood and a need to ensure our oceans are healthy, the MSC recognises this important contribution and the role FIPs play in improving fisheries’ health.

Many seafood companies choose to source from fisheries in FIPs when buying tuna and are also directly involved to help improve the sustainability of the fishery. Fisheries in FIPs are not MSC certified and seafood sourced from these fisheries must not make MSC claims or use the MSC ecolabel. Significant support and investment for these fisheries have encouraged the use of better management practices and data collection. Much of the investment has also been focused on delivering practical improvements in fisheries, such as modifications in fishing gear, operating procedures to reduce unwanted catch, and observer coverage programs to provide reliable data.

Recognising the need for long-term sustainability in these fisheries, some retailers have now included sourcing from FIPs in their tuna purchasing strategies to incentivise sustainable tuna fishing and meet responsible sourcing commitments. The MSC welcomes these commitments and has provided tools and guidance to support fisheries making real progress and improvements on their journey to MSC certification.

Comprehensive FIPs (see box) with action plans often still have significant sustainability challenges to overcome and can provide a route for fisheries to overcome these. For example, through significant investment as part of a FIP, the Cook Islands albacore and yellowfin longline fishery subsequently became MSC certified in 2015 (see page 56).

However, the effectiveness of FIPs can vary and when sourcing fish from a FIP, it is important to ensure that they meet minimum criteria: that their actions are transparent, that they clearly show improvement in fishery performance, and that these fisheries ultimately demonstrate this through a robust, independent assessment process.

The MSC has provided a definition of a credible FIP and a toolkit for FIPs that incorporates these principles. Find out more about FIPs at msc.org/fips

Tracking FIPs
FisheryProgress (fisheryprogress.org) is an excellent way of tracking active FIPs, rating them according to their progress and providing transparency.

Comprehensive FIPs
FisheryProgress defines Comprehensive FIPs as FIPS that “…aim to address all of the fishery’s environmental challenges necessary to achieve a level of performance consistent with an unconditional pass of the Marine Stewardship Council Fisheries Standard. Comprehensive FIPs engage a party experienced with applying the MSC Standard to complete an MSC pre-assessment to understand the challenges in the fishery and must have independent, in-person audits of progress against the MSC Standard every three years.”

The MSC’s Chain of Custody certification does not apply to FIPs. Therefore, any claims that tuna has been sourced from a FIP will need some form of alternative verification.
Some 25% of the world’s tuna catch is MSC certified. This means the state of the stock, environmental impacts and the management of the fishery have been rigorously assessed.

Global tuna catch estimated at 5.2 million tonnes in 2018 (landed weight) and expected to reach 7.3 million tonnes by 2024.

Global tuna market valued at US$11.59 billion in 2018 (landed value) and expected to reach US$14.40 billion by 2024.

MSC CERTIFIED TUNA FISHERIES – CASE STUDIES

The following case studies demonstrate the diversity of MSC certified tuna fisheries.

They comprise a mixture of tuna species and gear types and demonstrate a range of issues faced by tuna fisheries. Each example illustrates how the fishery has overcome its main challenges and how the fishery plans to keep improving through its certification.

The case studies are:

- AAFA & WFOA North & South Pacific albacore
- Cook Islands, Micronesia and Marshall Islands longline fisheries
- Echebastar Indian Ocean skipjack
- Maldivian skipjack
- North Atlantic albacore artisanal fishery
- North-eastern Tropical Pacific tuna
- PNA skipjack and yellowfin
- PT Citraraja Ampat, Sorong, skipjack and yellowfin
- Solomon Islands albacore, skipjack and yellowfin
- Tri Marine Western & Central Pacific skipjack and yellowfin
- Solomon Islands albacore, skipjack and yellowfin

These fisheries represent a subset of those found in the MSC program and a full list of all MSC certified tuna fisheries is available at fisheries.msc.org

MSC SCORING SYSTEMS

When a fishery is assessed against the MSC Fisheries Standard, it receives a score for each of 28 sustainability indicators.

Scores of 100 = Near-perfect
Scores of 80-99 = Global best practice
Scores of 60-79 = Acceptable performance
Scores of below 60 = Fail

If a fishery scores 60-79 for any indicator, it must improve its performance within a specified timeframe – normally the five-year duration of the certificate – in order to retain certification. Certified fisheries must score an average of at least 80 for indicators within each of the three Principles of the MSC Fisheries Standard.
Background
The American Albacore Fishing Association (AAFA) was the first tuna fishery to be certified in 2007. They started sharing certificates with the Western Fishboat Owners Association (WFOA) in 2014. They are non-profit associations and many of the vessels have been operated by the same families for generations.

There are distinct stocks of albacore in the North and South Pacific and these associations fish both stocks.

The fisheries use both trolling and pole and line fishing gears. Both methods are very selective as they catch the tuna one-by-one and monitor catches in real-time, so catch of non-target species is very low (less than 0.5% in both fisheries). The fisheries monitor their bycatch and implement management measures to reduce it. For example, if the fishermen are catching too many juveniles in a particular area, they move fishing location.

Selected conditions and improvements
The AAFA and WFOA fisheries have adopted a number of major improvements and addressed conditions to ensure long-term sustainability.

Stock Status
Through its original certification, AAFA and WFOA have established robust monitoring programs and management measures to protect the albacore stock e.g. by setting a tuna catch limit annually and carrying out monitoring and research programs to address areas of uncertainty.

However, neither of the fishery’s Regional Fisheries Management Organisations have yet adopted appropriate Harvest Control Rules to ensure the long-term health of the stocks, and this is a condition of certification. The fishery is on-track for achieving this and will pursue the adoption of HCRs over the coming years. In addition, the South Pacific fishery is required to implement a harvest strategy at the Western and Central Pacific Fisheries Commission (WCPFC) over the certification period.

Environment
Both the North and South Pacific albacore fisheries score highly because of their low impact on the environment: the fishery operates multiple measures to protect non-target and Endangered Threatened and Protected (ETP) species, such as marine mammals, turtles or seabirds. For example, the gear types used are very selective and they use barbless hooks for quick and safe release of any bycatch (see picture below). As such, the amount of unwanted catch is low (<0.5%) and interactions between ETP species and the fishery are deemed ‘highly unlikely’.

Management
Throughout its initial certification, the fisheries have implemented both domestic and international management policies for albacore, with robust short- and long-term objectives. Going forward, the South Pacific fishery will need to demonstrate that the WCPFC decision-making processes respond to the state of the albacore stock through an appropriate harvest strategy (condition 3).

The hooks are specifically designed to reduce bycatch. Hooks are un-baited and barbless, enabling the quick and safe release of bycatch and vulnerable species.
**Background**

The Cook Island’s longline fishery for yellowfin and albacore was first registered as a Fishery Improvement Project (FIP) on Fishery Progress in July 2013. It initially scored poorly on several attributes, particularly for its impact on the populations of the target stocks and other species. The fishery worked hard over the following years to determine the health of the stocks, developed practices to prevent impacts on Endangered Threatened and Protected (ETP) species and implemented data collection programs for non-target species. The fishery was MSC certified in 2015 and since then has addressed several of the conditions of certification.

The SZLC CSFC and FZLC fishing companies from the Cook Islands fishery then went on to certify their yellowfin and bigeye fisheries in the Federated States of Micronesia (FSM) in 2018, and in the Republic of the Marshall Islands (RMI) in 2019 (through the Marshall Islands Fishing Venture, a subsidiary of SZLC), and have now added bigeye to the recertification process in the Cook Islands.

The Micronesia fishery was the first time that bigeye had been certified to the MSC Standard, representing a turning-point for this previously overfished species.

To maintain the certification, important management measures will need to be agreed to safeguard bigeye tuna stocks – as a result, this certification could influence the sustainability of bigeye fishing across the entire WCPO.

**Selected conditions and improvements**

All these fisheries achieved certification as the result of fishery improvement projects and had already implemented a number of improvements prior to certification. As part of their certification, they will be making further progress to address specific conditions.

**Stock Status**

The most recent stock assessments show that stocks are at or above the MSY level. The certifications are all conditional upon the adoption of harvest strategies including HCRs, by all member states of the WCPO by 2021. These certifications therefore provide significant momentum for members to support the adoption of such measures, which are under development. There are effort constraining measures in place throughout the WCPFC area.

**Environment**

The fishery uses circle hooks to minimise bycatch of ETP species such as sharks and turtles, and ‘shark lines’ and wire leaders are banned.

The Marshall Islands’ observer coverage and information demonstrated that the fishery does not have significant impacts on any of the ecosystem components considered. In the Cook Islands, significant improvements have been made in the reporting of interactions with ETP species, and the FSM fishery is working towards a similar condition.

An electronic monitoring system is being trialled on several boats.

**Management**

The fishery is managed internationally through the WCPFC and nationally in each EEZ. In FSM, the robust management framework with clearly defined roles and responsibilities at national and regional level was regarded as a key strength. The Cook Islands’ fishery is on track to meet conditions around decision-making processes to ensure they are effective, transparent, inclusive and responsive, and take into account stakeholder concerns. The Marshall Islands is working towards strengthening its dockside inspection activities.
CASE STUDY
ECHEBASTAR INDIAN OCEAN SKIJPACK

Gear type: Purse seine (both non-entangling drifting FAD and free-school)
Tonnage: 33,866 tonnes (2018) | First certified: 9th November 2018

Background
The Echebastar fishery was the first drifting Fish Aggregating Device (dFAD) fishery to achieve MSC certification. It was certified on its second attempt following management improvements in the Indian Ocean including new FAD regulations.

The Echebastar fishery catches skipjack using purse seine nets that are set on free schools, and on non-entangling dFADs. Drifting FADs increase fishing efficiency, keeping prices low, but this can result in the bycatch of other species that are attracted to the FADs, making it harder for these fisheries to achieve MSC certification. However, the Echebastar certified fishery has substantially reduced catches of non-tuna species and of Endangered, Threatened and Protected (ETP) species to 3% and 0.38% of catches, respectively43.

The Echebastar fishery worked with the Indian Ocean Tuna Commission and Seychelles authorities to reduce bycatch by44:
• Reducing numbers of FADs over the last 3 years
• Using only non-entangling FADs
• Ensuring the rapid release of non-target species

The fishery has also added conveyor belts to three of its five vessels to rapidly release any unwanted catch directly back to the sea to increase survival rates. It also has 100% human observer coverage, providing high-quality data about the fishery and ensuring compliance with regulations and certification requirements. These efforts demonstrate leadership within the tuna fishing industry.

Selected conditions and improvements
The Echebastar fishery has made major improvements and committed to deliver conditions of certification to ensure long-term sustainability. Following the first surveillance audit, all conditions were either on target or ahead of target.

Stock Status
The Echebastar fishery received top scores for stock status and monitoring. The Indian Ocean skipjack stock is at a healthy level with Harvest Control Rules in place to ensure its future sustainability46, and stock assessments are regularly conducted to inform management. New conditions were raised in the latest surveillance report to strengthen the harvest strategy and ensure catch limits are not exceeded.

Environment
Before their first assessment, the fishery had implemented 100% observer coverage, providing a high level of assurance of compliance and data quality. The Echebastar fishery has already reduced the number and impact of its FADs (see box) and has also committed to addressing further conditions to allow environmental impacts to be measured:
• Collecting further evidence about the impact of FADs on ETP species and on vulnerable marine ecosystems, to sufficiently measure their impacts and demonstrate that dFADs are highly unlikely to reduce structure and function of coral reefs to a point where there would be serious or irreversible harm46. The fishery is already making progress on improving the efficiency, quality and quantity of observer data and makes it publicly available
• Using this evidence to establish a precautionary strategy to ensure that it is highly unlikely that derelict dFADs could reduce structure and function of the coral reefs to a point where there would be serious or irreversible harm
• Collecting sufficient evidence to allow for identification of the main impacts of derelict dFADs on coral reefs, and ensuring there is reliable information on the spatial extent of interaction and on the timing and location of use of the fishing gear

Management
There is a strong basis for management through the IOTC, EU management and Seychelles national measures. While information is available on the fishery’s performance and management actions, there is a lack of transparency for actions and decision-making for private deals in the fishery. Therefore, through condition 8, the Echebastar fishery must ensure that any management decisions including private agreements are appropriately explained and available for stakeholders.
Background

Fishing is central to the Maldivian culture, economy and heritage: the country celebrates its fishing heritage each year on 10th December, the National Fishermen’s Day. Tuna are the Maldives’ primary export and support 30,000 livelihoods. Fishing began on masdhonis, wooden boats – powered by sails and oars – with an open deck to land the fish and carry live bait. Mechanisation of the fleet started in 1974, when a single masdhoni was equipped with a small diesel engine. By 1981, over 800 masdhonis were mechanised and accounted for 92% of the masdhoni tuna catch. To go tuna fishing, around 10-18 fishermen leave the port in Malé (or from any one of 200 or so inhabited islands) on an overnight trip. The fishermen use the centuries-old pole and line technique, which is believed to have been invented in the Maldives and contributes more than 70% of the total tuna landings in the Maldives.

The fishery is highly selective, yielding very low levels of non-target bycatch (0.65%). However, the fishery increasingly required more bait per trip as pole and line vessels became larger and trips started to last longer than the traditional one day. To ensure that bait stocks remain at a healthy level the Maldives have successfully implemented a management plan to ensure that baitfish fisheries are sustainable through a live bait management plan, which included: objectives on bait use; strengthening data capture – training the fishermen to report bait use; and carrying observers to corroborate fishermen’s logbook data.

Management

The Maldives’ initial certification was criticized by WWF in 2012 because they felt the IOTC did not have adequate HCRs to pass an MSC assessment. The fishery had committed to achieving well-defined HCRs at the IOTC. The Maldives, supported by other Indian Ocean coastal states and the International Pole and Line Foundation (IPNLF), led the efforts to ensure that a framework was put in place for improved management of skipjack stocks. This commitment, combined with intervention by the retail sector, encouraged the IOTC to adopt formal HCRs for skipjack in 2016. This was a significant success for both the Maldives fishery and the MSC program. By adopting this measure, the IOTC protects the health of the Indian Ocean skipjack stock for the future.

Logbooks are an important part of data collection, showing population trends for tuna, bycatch, bait and endangered species. The Maldives fishery has committed to improving compliance with logbook returns, which are now mandatory and must be provided prior to catch being landed. As a result, the fishery is ahead of target on its only condition.

Selected conditions and improvements

The Maldives fishery has implemented major improvements to ensure long-term sustainability. The fishery fulfilled all the conditions required under its initial certification. Under its current certification, it only has one condition.

Stock Status

The skipjack population is healthy and is subject to research, monitoring and stock assessments on a regular basis. An HCR is in place through the IOTC – there are no conditions.

Environment

Using pole and line, fishers can target specific species and only land those that they actively seek to catch, avoiding unwanted bycatch – interactions with ETP species are negligible. The bait species used by pole and line fisheries need to be properly managed. In 2013, the Maldives fishery addressed conditions from its initial certification to ensure that baitfish fisheries are sustainable through a live bait management plan, which included: objectives on bait use; strengthening data capture – training the fishermen to report bait use; and carrying observers to corroborate fishermen’s logbook data.

Management

The Maldives’ initial certification was criticized by WWF in 2012 because they felt the IOTC did not have adequate HCRs to pass an MSC assessment. The fishery had committed to achieving well-defined HCRs at the IOTC. The Maldives, supported by other Indian Ocean coastal states and the International Pole and Line Foundation (IPNLF), led the efforts to ensure that a framework was put in place for improved management of skipjack stocks. This commitment, combined with intervention by the retail sector, encouraged the IOTC to adopt formal HCRs for skipjack in 2016. This was a significant success for both the Maldives fishery and the MSC program. By adopting this measure, the IOTC protects the health of the Indian Ocean skipjack stock for the future.

Logbooks are an important part of data collection, showing population trends for tuna, bycatch, bait and endangered species. The Maldives fishery has committed to improving compliance with logbook returns, which are now mandatory and must be provided prior to catch being landed. As a result, the fishery is ahead of target on its only condition.
**Background**

The fishery targets albacore in the Bay of Biscay and adjacent waters using pole and line and trolling fishing techniques. These are traditional methods that keep the fish in good condition and result in almost no bycatch.

The fishery was first certified in 2016, and the certification subsequently extended to additional fleets in 2019. 164 vessels, fishing from the regions of Cantabria, Guipuzcoa, Vizcaya and Asturias in Spain, are involved in the fishery.

**Selected conditions and improvements**

The initial assessment of the fishery raised three conditions for both gear types, and two additional conditions for the pole and line fishery. A number of improvements have been made on the basis of these conditions and the fishery demonstrates best practice in several areas.

**Stock status**

Albacore is a temperate tuna widely distributed throughout the Atlantic Ocean and Mediterranean Sea. The stock status is assessed by ICCAT, and has been improving in recent years. The stock biomass in 2015 was above the MSY level. The fishery proactively contributed to the development and adoption of a regional set of harvest control rules by ICCAT, and has fully implemented them, addressing two conditions. This was reflected in the recent P1 upgrading audit in which every indicator scored over 80 and no conditions were set.

**Environment**

Two conditions were established for the pole and line fleet to improve information to ensure that the direct effects of the fishery on any Endangered, Threatened and Protected (ETP) species are highly unlikely to create unacceptable impacts on these species. These conditions are still being worked on by the fishery. The fishery is highly selective (98% of catches are of the target species) and no or very low levels of interaction with ETP species have been recorded by observers.

**Management**

Compliance within the fishery is very strong and new fishery-specific regulations have been introduced that establish objectives for the fishery. In 2017, ICCAT adopted an interim HCR for albacore, which will ensure the stock status is maintained in the future. The certified fleet has adopted a code of conduct that sets out action to be taken in the case of interactions with cetaceans, birds or turtles to ensure their safe release and maximise survival.

---

© AZTI / MSC
Background

Fishing takes place in the Eastern Tropical Pacific Ocean (EPO) in the Inter-American Tropical Tuna Commission (IATTC) management area. There are 35 purse seine vessels from Mexico involved in the fishery, from four independent fishing companies, that formed the Pacific Alliance for Sustainable Tuna (PAST). They catch both yellowfin (85% of the total catch) and skipjack (15% of the total catch). In the tropical waters of the Eastern Pacific Ocean, yellowfin tuna schools often swim together with large pods of different species of dolphins.

This behaviour appears to reduce the risk of predation to the tunas when they swim in the surface waters due to low oxygen levels in the warm waters66. This tuna-dolphin association is used to find and catch the tuna.

Vessels fishing in the EPO were highly criticized due to poor fishing practices in the 1970s and 1980s which led to high levels of dolphin bycatch (see graph). A number of campaigns highlighted this issue and encouraged consumers to avoid tuna caught from dolphin-associated purse seine fisheries in the EPO. PAST vessels started fishing in the 1990s and have spent the last 30 years investing in science, research, management and international agreements for long-term sustainability. Between 1985 and 1997, dolphin mortalities dropped by 99% and the fishery was awarded the Margarita Lizárraga Medal by the United National Food and Agriculture Organization in 2005. Different techniques and manoeuvres are used to ensure that dolphins and other marine animals like sharks and sea turtles are released safely from the nets before bringing the tuna catch onboard.

Estimated dolphin bycatch in the EPO purse-seine tuna fishery

Selected conditions and improvements

The Mexican fleet of this international fishery has recently been certified and is working towards addressing a number of conditions related to stock status, ETP species and management.

Stock status

The fishery is working towards developing reference points for skipjack and a harvest strategy that is responsive to the state of the stock, through the IATTC. Skipjack biomass and recruitment have been increasing over the past 20 years, and were above their upper reference levels in 2016 and 2017. For yellowfin, the spawning biomass has been fluctuating around the MSY level, and the last estimated index is above it, due to high recruitment from 2015 to 201746.

Environment

The fishery actively implements a number of measures to ensure that dolphins are able to escape the nets, and actively help to release them (see box). The number of dolphin mortalities by the PAST fleet and whole IATTC fleet has reduced significantly (see graph). Over 95% of dolphin-associated sets result in zero dolphin mortalities. Further ongoing evaluation is needed to fully assess the level of unreported or unobserved dolphin mortalities and the fishery is collecting data to enable this.

Management

The fishery is on track to meet conditions around decision-making processes to ensure they are effective, transparent, inclusive and responsive, and take into account stakeholder concerns. This will help ensure best practice in the development of Official Mexican Standards (rules/regulations) and management plans for the tuna fishery. Additionally, the fishery is working towards ensuring that national authorities identify infractions, better enforce relevant management measures and consistently apply sanctions for non-compliance. The fishery implements 100% independent observer coverage68.

Ensuring non-tuna species are safely released from the nets

Each team of fishermen works proactively to minimize the impact on the ecosystem, including aiming for 100% live release of all non-target species. They use specially designed nets that incorporate fine-mesh safety panels which allow non-tuna species to swim clear of the net, and perform a special manoeuvre at the end of the set to release the unwanted catch. In addition, highly specialized and trained divers manually assist any remaining dolphins to escape the net prior to hauling.
**CASE STUDY**

**PNA SKIPJACK AND YELLOWFIN**

**Gear type:** Purse seine free-school  | **Tonnage:** 735,523 tonnes (2018)

**First certified:** 21st December 2011; re-certified: 23rd March 2017

---

**Background**

The Parties to the Nauru Agreement (PNA) are a group of eight island countries in the Pacific (see map above). They formed The Nauru Agreement in 1982 to harmonise fisheries management in their Exclusive Economic Zones. The first agreement mandated members to implement minimum fisheries management measures. This has developed over time. They now limit the number of days that vessels can fish and they have negotiated agreements with other nations including the United States.

PNA successfully restricted and reduced tuna exploitation, enabling the fishery to achieve MSC certification in 2011. It is the world’s largest independently certified tuna supplier. A quarter of the world’s tuna and half the global population of skipjack live in PNA waters. By taking collective control of their waters, ensuring sustainable fisheries and using a geographic indicator through the Pacific platform, they have been able to sell their product with the MSC ecolabel, giving a significant economic boost to these small island states.

**Selected conditions and improvements**

The PNA fishery has implemented significant improvements to ensure its long-term sustainability.

**Stock Status**

Both tuna stocks are healthy and the PNA has developed thresholds for further protection. Stock assessments are regularly carried out and there is an extensive programme of research. The PNA will need to ensure its harvest strategy is responsive to both stocks’ status (conditions 1 and 3) and will need to demonstrate that well-defined Harvest Control Rules are in place (conditions 2 and 4) through the Western and Central Pacific Fisheries Commission (WCPFC).

**Environment**

The PNA fishery has delivered on its goals to reduce unwanted bycatch and Endangered, Threatened and Protected (ETP) species catch: many PNA members banned shark finning (see box) and setting purse seine nets on whale sharks in 2012. The fishery has minimal bycatch – 98.5% of the catch is of the target species. The fishery adopted 100% observer coverage and a Good Practice Guide for handling ETP species.

Going forward, the fishery will implement a strategy to ensure the fishery does not hinder the recovery of manta rays and devil rays (conditions 5 and 6). Additionally, the retention of Silky and Oceanic white tip sharks is prohibited.

**Management**

The PNA has implemented a fishery-specific management system with effective decision-making processes. The fishery scored especially well for its collaboration efforts at the WCPFC, and has no conditions related to management. There is a comprehensive monitoring, control and surveillance system in place.

---

**CHALLENGES**

**Compartmentalisation**

Like other free-school purse seine fisheries, boats fish both on free-school tuna and FADs and fish within and outside the certified EEZ area. The MSC-eligible fish are kept separate on-board and 100% observer coverage ensures they are not mixed.

The fishery has implemented satellite tracking and batch coding (ensuring traceability). Only the MSC-eligible free-school tuna is MSC certified on landing. PNA uses the MSC premium as an economic incentive to compliment other measures to limit FADs and promote sustainability. This has been described as “the MSC theory of change in practice”. Following concerns raised by stakeholders about the sustainability of fishing activities which carry out both certified and uncertified fishing practices in a single trip, the MSC is introducing changes which will require all fishing practices used within the fishery (both free-school and FAD-associated purse seine sets) to be certified by March 2023 (see page 30). The MSC is working with the PNA fishery and others to support the more sustainable use of FADs.

**Shark finning**

Shark finning has historically taken place in the PNA fishery. On average around 185 incidents were reported per year in 2013 and 2014. Since 2013, the MSC Fisheries Standard has required fisheries to demonstrate the likelihood that shark finning is not taking place at the point that they are first certified, or recertified. Ahead of this requirement, the PNA governments were already taking robust action to ban shark finning. The WCPFC also has conservation and management measures in place to prevent shark finning. Following these regulations, shark finning has been virtually eliminated from the fishery, with just 3 instances reported in 2017 (0.05% of the total catch). Following new requirements for shark finning effective from September 2020, the fishery will need to take further steps to remove any organisation or company found to have undertaken shark finning from its certificate (see page 32).
Background

This was the first fishery in Indonesia to become MSC certified\(^6\) – a significant development since Indonesia is the world’s leading tuna producer and second largest seafood producer. The skipjack and yellowfin stocks in the Western Central Pacific Fisheries Commission (WCPFC) represent 60% of the world’s tuna catch\(^6\). The fishery is also important for the local economy, employing 750 local fishermen\(^6\).

PT Citraraja Ampat Canning (PT CRA) is a fish packing, processing and exporting company, based in Indonesia and founded in 1992. One of its main products is canned Indonesian tuna, which it sources from pole and line fisheries.

It works with local traditional pole and line fishermen in Sorong, who use the centuries-old tradition of pole and line fishing.

Tuna is integral to Indonesia’s fishing economy and illegal fishing costs Indonesia US$4 billion in lost profits each year, hampering the health of Indonesia’s seas and food security. Indonesia’s Government has demonstrated a clear commitment to end illegal fishing by sinking illegal fishing boats. While successful in severely reducing the yields of illegal fleets, destroying vessels does not alone achieve sustainability. Crucially, sustainable fishing requires effective management (see box).

To catch the tuna, anchored Fish Aggregating Devices (aFADs) and live bait first attract tuna to the boat. Fishermen use poles and lines to catch the tuna one by one\(^6\). Tuna are then swung on board and immediately put into holds on ice. The fishery catches virtually no Endangered, Threatened or Protected species, and any unwanted catch is released safely\(^6\).

Selected conditions and improvements

The fishery has implemented a number of improvements to ensure long-term sustainability.

Stock Status

Both stocks are healthy and are subject to regular stock assessments. The fishery will work with the WCPFC to ensure that the harvest strategies are responsive to the state of both stocks and well-defined Harvest Control Rules (HCRs) are implemented.

Environment

There are no conditions relating to environment: the fishery is very selective, using barbless, unweighted and un-baited hooks; there is 100% observer coverage; and there is a National Plan to ensure no shark finning occurs.

Management

National and international laws are in place to protect the stocks and decision making, consultation and compliance at a local level are good. Indonesia cooperates with the WCPFC, however, both parties need to work together to implement harvest strategies with HCRs, and Indonesia needs stronger management objectives to deliver outcomes and consistently implement RFMO requirements at the national level.

Reducing illegal fishing is not enough

Legal fishing needs to be well-managed to ensure sustainability. Illegal fishing represents over 30% of the total catch of the WCPFC, costing Indonesia US$4 billion in profits every year\(^6\). To tackle illegal fishing, Indonesia’s Government seized and sank 488 (mostly foreign) illegal vessels between October 2014 and August 2018\(^6\), and as well as banning foreign fishing in their EEZ, leading to a 30% reduction in vessel numbers. However, Indonesia’s future skipjack yields do not just rely on reducing illegal fishing, but also on effective management of legal fishing. If illegal fishing is reduced, but management is open access, both the harvest and profits will decrease in the future. Conversely, with appropriate management, stable and improved future harvests and profits are projected. Therefore, regional cooperation and effective management in Indonesia’s tuna fisheries have an opportunity to play a crucial role in its future sustainable development\(^6\).
**CASE STUDY**

**SOLOMON ISLANDS ALBACORE, SKIPJACK AND YELLOWFIN**

**Gear type:** Purse seine (anchored FAD and free school), pole and line, longline  
**Tonnage:** 39,113 (2017/18) | **First certified:** 12th July 2016

**Background**

The Solomon Islands tuna fisheries target skipjack, yellowfin and albacore in the Solomon Islands’ Exclusive Economic Zone and archipelagic waters. These certified tuna fisheries are extremely important to the economy, employing over 2,000 Solomon Islanders, and are one of the country’s largest private sector employers70.

Pole and line fishing is very selective with minimal bycatch. Pole and line fishing uses baitfish, and the fishery monitors its bait use. However, most of the tuna from this area is caught using purse seines deployed on free-schools and anchored Fish Aggregating Device (FADs) (see pages 18-25). Unwanted bycatch is discouraged as the fishery retains everything they catch.

Having certified its purse seine and pole and line tuna fleets in 2016, National Fisheries Development in the Solomon Islands went on to achieve certification for its longline fleet as well, providing coverage of all the main tuna gear types in its waters.

**Selected conditions and improvements**

The Solomon Islands’ fishery has adopted major improvements and addressed conditions to ensure long-term sustainability.

**Stock Status**

The stocks are healthy and regular stock assessments are carried out. The Solomon Islands, as part of the WCPFC, has no formal Harvest Control Rules (HCRs) in place for skipjack, yellowfin or albacore. Therefore, the fishery has been working with the Western Central Pacific Fisheries Commission (WCPFC) to develop harvest strategies and HCRs (conditions 1-4). The fisheries are on target to achieve these conditions for skipjack and yellowfin. The recent certification of the longline fleet means HCRs will also be pursued for albacore.

**Environment**

In 2014, the fishery implemented a policy to retain all its catch. This went beyond the compliance requirements of the WCPFC. Although non-target species form a very small part of the catch, they provide an important protein source for the local population and landing them improves data collection in the fishery71. The fishery follows regulations to protect Endangered, Threatened and Protected (ETP) species, including prohibiting shark finning64, avoiding fishing near marine mammals, and safely handling any caught sea turtles. To corroborate information from logbooks, the fishery operates 100% observer coverage on purse seine trips64 and their compliance rates are proven to be high.

The Solomon Islands’ anchored FAD fishery scores particularly highly in relation to habitats. The fishery tries to recover old and lost FADs to reduce marine debris64, anchors FADs away from reefs to protect corals and is developing an anchored FAD management plan.

The recently-certified longline fishery will be working towards meeting conditions on information on the bait used in the fishery and levels of observer coverage to ensure ETP species are being protected.

**Management**

Since its certification, the fishery has achieved one of its main conditions, to make decision-making more transparent. It has achieved this through increased participation and appropriate representation in meetings and increased liaison with Government departments64. The fishery is also limited by the number of days fishing allowed annually, and there is a baitfish management plan in place as well as monitoring, compliance and surveillance requirements. Effort limitation was introduced for longline vessels in 2016.

“This is the first time that all three major gear types for tuna have been certified in the same fishing grounds, demonstrating a rare example of well-balanced management.” Bill Holden, MSC Senior Tuna Fisheries Outreach Manager
**Background**

The Tri Marine fishery was first certified in 2016. The fishery covers a wide expanse of the Pacific Ocean, extending beyond the waters of the Parties to the Nauru Agreement area to include the waters of the United States’ territorial waters, several Pacific Islands Forum Fisheries Agency member countries, and the high seas, within the Convention Area of the Western Central Pacific Fisheries Commission (WCPFC) RFMO.

The certified part of the fishery targets free-swimming schools of mature tuna, which helps to reduce the incidental bycatch of non-target species. Skipjack and yellowfin comprise almost 100% of the total catch so there is virtually no unwanted bycatch72.

**Selected conditions and improvements**

The Tri Marine fishery has implemented major improvements and addressed conditions, to ensure long-term sustainability.

**Stock Status**

The WCPFC has been slow to implement Harvest Control Rules for both stocks but has committed to implement these over the coming years65. However, the fishery, through the WCPFC, has developed reference points for skipjack and limits for the number of days that vessels can fish.

**Environment**

A key achievement is the introduction of 100% observer coverage in the fishery to provide assurance around shark finning claims. Observer records have demonstrated that there have been zero shark finning incidents from 2013-2018. The efficacy of observer coverage is currently being tested by installing cameras on vessels. Shark finning is prohibited under United States legislation and the fishery complies with the Shark Conservation Act (requiring that any sharks are landed with fins naturally attached)73. By committing to all these measures, the fishery has successfully addressed condition 5 of its certification.

The fishery has implemented management measures to reduce the impact of Fish Aggregating Device (FADs) on the environment. The fleet complies with WCPFC-mandated FAD closures i.e. three-month closure in the entire WCPFC Convention Area, plus an additional two-month FAD closure in the high seas. Non-entangling FAD designs have been employed and the fleet is in the process of testing biodegradable FADs. The revision of the MSC requirements in relation to compartmentalisation (see page 39) means that in the future the fishery will need to seek certification for their entire catch.

**Management**

The Tri Marine fishery has developed transparent non-compliance procedures – including charges, penalties and enforcement decisions – to deal with fishing infringements. The working group on compliance reviews and recommends compliance measures in the fishery using data supplied through logbooks, licences, vessel monitoring systems and observer reports. By adopting these procedures, the fishery has addressed condition 6, ahead of schedule.

---

**Gear type:** Purse seine (free school)  |  **Tonnage:** 9,939 tonnes (2019)  
**First certified:** 2nd June 2016

### WHY SHOULD I CHOOSE MSC CERTIFIED TUNA?

- **Buy with confidence**
  - Traceability from ocean to plate, preventing illegal fishing and mislabelling.

- **Assurance**
  - Independent certification bodies regularly check the fishery against the MSC Standard, which is developed by experts and with international consultation.

- **Safeguarding livelihoods**
  - Tell the stories of people involved in fisheries; certified tuna supports livelihoods for the future.

- **Protecting our Blue Planet**
  - Certified fisheries support healthy ecosystems, with low levels of non-target catch.

- **Recognising the importance of transparent, comprehensive FIPs**
  - A global network of NGOs and tuna supply chain representatives driving tuna fisheries towards sustainability by taking a collaborative partnership approach helping lay the foundation for future MSC certified fisheries.

- **Meeting global commitments**
  - Certified fisheries support global food security, contributing to the UN Sustainable Development Goals.

- **Fish for the future**
  - Sustainability based on science; strong management and good governance helps to ensure supplies of tuna for the future.

- **Being innovative**
  - Research and innovation in sustainable fishing, driving improvements in global fishing.

- **Availability**
  - Around 25% of the global tuna catch is MSC certified.

- **Drive change**
  - More fisheries want to become sustainable. Support them in their journey.
CONSUMER INSIGHTS

Over 25,000 consumers (18,909 seafood consumers) in 22 countries took part in the research, which ensured a statistically representative sample in each country.

72% of those surveyed said there is a need for brands and supermarkets to independently verify their claims about sustainability (up from 68% in 2016).

70% of seafood consumers say they’d like to hear more from companies about the sustainability of their seafood products.

83% believe that seafood needs to be protected for future generations.

41% of seafood consumers recognise the blue MSC label.

As the world’s most recognised seafood labelling and certification program, consumers are positive that the MSC, and the thousands of organisations committed to using the blue MSC label, are contributing to the health of the world’s oceans.

82% of consumers rate the MSC highly for helping to recognise and reward sustainable fishing.

83% agree that the MSC label helps to identify sustainable seafood quickly and easily.

70% of seafood consumers agree that in order to save the ocean, we have to consume seafood only from sustainable sources.

Data from: GlobeScan. 2018. Demand for independent labelling of seafood is increasing globally. Consumers surveyed were in Australia, Austria, Belgium, Canada, China, Denmark, Finland, France, Germany, Italy, Japan, the Netherlands, New Zealand, Norway, Poland, Singapore, South Africa, Spain, Sweden, Switzerland, UK and USA. China was surveyed for the first time in 2018. Available at: https://www.msc.org/docs/default-source/default-document-library/for-business/msc-consumer-survey-2018-results.pdf?sfvrsn=b2c35ca2_4.
CONCLUSION

Tuna are among the most commercially valuable fish on the planet. To ensure their productive and stable future supply, tuna need to be responsibly managed and sustainably fished. This handbook comes at an important time. It aims to unpack the complex and diverse nature of the global tuna supply chain by providing information on issues related to tuna fishing such as gear types, fishing methods, species, sustainability, and environmental impact. Retailers and buyers can help support sustainable tuna fishing by ensuring they source from certified sustainable fisheries and by encouraging fisheries to make improvements to safeguard their sustainability.

Tuna fisheries can be associated with major supply chain risks such as overfishing, the bycatch of threatened and endangered species, shark finning, and forced labour practices. Minimising these risks requires rigorous and regular checks on compliance at every point along the supply chain. As highlighted in this handbook, simple approaches, such as sourcing from or avoiding particular fishing methods, do not sufficiently reduce the full range of potential environmental impacts associated with tuna fishing, and importantly, do not necessarily prevent overfishing of stocks.

Fishery Improvement Projects (FIPs) are a vital step towards delivering sustainable tuna fisheries. Comprehensive FIPs that operate transparently and that are making measurable progress are a crucial tool to help fisheries work towards becoming sustainable and achieving MSC certification.

The best way to reduce risk and ensure tuna is sustainable is to source from MSC certified tuna fisheries. The MSC has developed a universal seafood certification standard that is recognised as the most credible and robust standard for environmentally sustainable fisheries. It assures that the stocks are healthy, the impact on the ecosystem is minimised and the fishery is well-managed, driving improvements over time. Coupled with the Chain of Custody Standard for traceability, this provides credible assurance for buyers and retailers that the tuna they are sourcing originates from a sustainable fishery.

MSC certified fisheries are helping to secure healthy tuna stocks around the world, which are essential for the health of the marine environment and global fishing economies. The MSC program is also helping to meet the UN Sustainable Development Goals for global food security and equality including SDGs 2, 8, 12, 14 and 17.

Consumers’ appetite for MSC certified seafood is increasing. Consumers believe that safeguarding our seas is vital for our future, and across 21 countries, consumers rate sustainability more highly than price and brand.

The MSC is helping satisfy this demand by delivering sustainable, healthy and tasty solutions to our partners and consumers. Nearly 25% of global tuna is now MSC certified and 74% of consumers who know the MSC brand, say they trust it. By sourcing MSC certified tuna, you are not only investing in ensuring stable supplies of fish for the future, but also incentivizing healthy oceans and coastal communities.

KEY ACTIONS

- For confidence in the sustainability and traceability of tuna, choose tuna from MSC certified fisheries
- Retailers, NGOs and fishing companies need to work together to influence RFMOs to adopt the measures needed to maintain MSC certification. Contact your Fisheries Minister or RFMO delegation in the coastal state where you source your tuna, and encourage them to support the adoption of Harvest Control Rules at the RFMO meetings
- Exercise caution over the use of single-issue claims such as FAD-free, particularly when they are not backed by traceability programs
- Stay up-to-date and take part in our consultation processes: we are continually developing our Standard to ensure that it tackles key issues in fisheries and continues to reflect widely accepted international best practice
- Share your sustainability credentials with your customers, whether they are supermarkets or a consumer
- Join the following groups that are supporting improvements in tuna fisheries: Global Tuna Alliance, International Seafood Sustainability Foundation (ISSF), RFMO working groups or scientific committees, Seafood Business for Ocean Stewardship (SeaBOS), NGO Tuna Forum, Global Dialogue on Seafood Traceability (GDST), ProActive Vessel Register
- Ask your supplier questions about the fishery you are sourcing from, for example, regarding catches of non-target species in the fishery. There is always room for improvement to ensure sustainability within tuna fisheries

25% of global tuna is now MSC certified
74% of consumers who know the MSC brand, say they trust it.
